## **Detailed Explanation of Stata Code for Marginal Effect Plot**

Below, I go through the Stata code for creating the sample marginal effect plot shown on my webpage. The interactive model associated with this marginal effect plot has the following basic form:

$$Y = \beta_0 + \beta_1 X + \beta_2 Z + \beta_3 X Z + \epsilon. \tag{1}$$

```
version 11.0
#delimit;
log using "C:\matt\publications\jop2\webpage\marginal_effect_plot.log", replace;
set more off;
```

The first line simply indicates the version of Stata that is being used. The second line tells Stata that all command lines are finished with a semi-colon. The third line opens a log file and indicates where it will be saved. The fourth line tells Stata not to pause when running the do-file.

This part of the code is how I like to start all do-files and is not strictly necessary to create the sample marginal effect plot. It indicates the name of the do-file, the date on which it was written, the author, the purpose of the do-file, the data used with the do-file, the name of the associated log file, the name of any new data set that is created by the do-file, the name of any previous do-file or data set, and where the do-file was run.

```
use "C:\matt\publications\jop2\webpage\alexseev.dta", clear;
```

This tells Stata what data set to open and where to find it. It also clears any existing data in Stata's memory.

```
set obs 10000;
```

This command sets the number of observations (rows) in the data set to 10,000. There is nothing special about this number. You will want to calculate the marginal effect of some variable, say X, at multiple values of some modifying variable, say Z. If you want to calculate the marginal effect at more values than you actually have in your original data set, then you will need to increase the number of observations in the data set. This is precisely what this line of code does.

```
regress xenovote slavicshare changenonslav slavicshare_changenonslav
inc9903 eduhi02 unemp02 apt9200 vsal103 brdcont, cluster(region);
```

This line estimates the chosen model. In this case, XENOVOTE is the dependent variable, Y, SLAVICSHARE is our X, CHANGENONSLAV is our Z, SLAVICSHARE\_CHANGENONSLAV is our  $X \times Z$ , INC9903 EDUHI02 UNEMP02 APT9200 VSALL03 BRDCONT are control variables, and CLUSTER(REGION) indicates the use of robust standard errors clustered by REGION.

```
matrix b=e(b);
matrix V=e(V);

scalar b1=b[1,1];
scalar b2=b[1,2];
scalar b3=b[1,3];

scalar varb1=V[1,1];
scalar varb2=V[2,2];
scalar varb3=V[3,3];

scalar covb1b3=V[1,3];
scalar covb2b3=V[2,3];

scalar list b1 b2 b3 varb1 varb2 varb3 covb1b3 covb2b3;
```

The first two lines grab the elements of the estimated coefficient vector and the variance-covariance matrix that are necessary to calculate the marginal effects and confidence intervals in the marginal effect plot. The estimated coefficient vector, b, is  $1 \times k$ , where k is the number of covariates including the constant term. The first element in b, b [1,1], is  $\beta_1$ , the second element, b [1,2] is  $\beta_2$ , and so on. The last element in b is the coefficient on the constant term,  $\beta_0$ . The estimated variance-covariance matrix is V. The diagonal elements indicate the variances of the coefficients, while the off-diagonal elements indicate the covariances of the coefficients. For example, the element V [1,1] indicates the variance of  $\beta_1$  and the element V [1,3] indicates the covariance between  $\beta_1$  and  $\beta_3$ . The remaining lines of code create (and then list) scalars that are equal to the coefficients and variances that are needed to calculate the desired marginal effects and standard errors. You can check the listed scalars with the regression output to make sure that you have done everything correctly.

These lines calculate everything that is necessary to produce the top panel of the marginal effect plot shown on the webpage. The first line is important and generates a variable MVZ that takes on all of the values of the modifying variable Z for which you want to calculate the marginal effect of X; the more values, the smoother your marginal effect line will be. \_n in Stata indicates the observation number starting at 1. If your modifying variable starts at 1 and increases in increments of 1, then you could simply type generate  $\text{MVZ=\_n}$ ;. If your modifying variable starts at 0 and increases in increments of 1, then you would need to start at \_n-1, and so you would type generate  $\text{MVZ=\_n-1}$ ;. If you have a continuous modifying variable that starts at 0 and you want to calculate the marginal effect of X at each 0.01 increment in the modifying variable Z, then you would type generate  $\text{MVZ=}((\_n-1)/100)$ ;. The modifying variable Z in our specific example starts at -1.99 and I would like to calculate the marginal effect of X at each increment of 0.01 in the modifying variable Z: generate  $\text{MVZ=}((\_n-200)/100)$ ;.

The second line determines the last value of the modifying variable Z for which you want to calculate the marginal effect of X. Given how it has been constructed, MVZ = 13 when  $\_n = 1501$ . Since the highest observed value of Z in my data is 13, I replace MVZ as ., or missing, for all values of  $\_n>1501$ .

The third line calculates the marginal effect of X on Y, conbx, for the desired values of the modifying variable Z. The marginal effect of X for an interactive model like that shown in Eq. 1 is:

$$\frac{\partial Y}{\partial X} = \beta_1 X + \beta_3 Z. \tag{2}$$

The third line calculates this marginal effect of X for all values MVZ, so long as MVZ is less than 13.

The fourth line calculates the standard error for the marginal effect of X on Y, consx, for the desired values of the modifying variables of Z. The standard error for the marginal effect of X for an interactive model like that shown in Eq. 1 is:

$$\sqrt{\operatorname{var}(\beta_1) + Z^2 \operatorname{var}(\beta_3) + 2Z \operatorname{cov}(\beta_1 \beta_3)}.$$
 (3)

The fourth line calculates the standard error for the marginal effect of X for all values MVZ, so long as MVZ is less than 13.

The last three lines use the standard errors and marginal effects to create two-tailed 95% confidence intervals. The critical value for the t statistic if you have more than 120 degrees of freedom is 1.96. If you have fewer degrees of freedom or want to calculate confidence intervals for a different level of significance, then you will have to change the critical value for the t statistic. lowerx and upperx capture the lower and upper value, respectively, for the two-tailed 95% confidence interval around the marginal effect of X.

```
gen consz=sqrt(varb2+varb3*(MVX^2)+2*covb2b3*MVX) if _n<990;
gen az=1.96*consz;
gen upperz=conbz+az;
gen lowerz=conbz-az;</pre>
```

These lines calculate everything that is necessary to produce the bottom panel of the marginal effect plot shown on the webpage. The difference is that we are now plotting the marginal effect of Z on Y across all of the observed values of the modifying variable X, MVX. In this case, the observed values of X run from 0 to 99, and I want to calculate the marginal effect of X on Y at 0.1 increments in X.

```
gen where=-0.045;
gen where2=-1.01;
gen pipe = "|";
egen tag_nonslav = tag(changenonslav);
egen tag_slavic = tag(slavicshare);
```

These lines create the necessary information if you want to include a rug plot in both panels of the marginal effect plot. Whether you want to include a rug plot will likely depend on the sample size; they are less useful when the sample size is large. Unfortunately, Stata does not have a command for producing a rug plot, and so you have to produce it manually as is the case here. The first two lines indicate *where* the rug plot will be located relative to the horizontal axis in the upper and lower panels of the marginal effect plot. You will have to play around with these numbers so that they are appropriate for your particular marginal effect plot; the values associated with where and where2 are related to the scale used in the panels. The third line creates the vertical symbol that will be used in the rug plots. The last two lines prevent Stata from having to overwrite symbols for observations that have the same value. For more information on how to construct rug plots in Stata, see here.

```
gen yline=0;
```

This will create a horizontal line at 0 on the vertical axis. This line will enable us to easily see when the marginal effect is greater or smaller than 0.

```
yscale(noline alt)
yscale(noline alt axis(2))
xscale(noline)
legend(off)
xtitle("", size(2.5))
ytitle("", axis(2) size(2.5))
xsca(titlegap(2))
ysca(titlegap(2))
scheme(s2mono) graphregion(fcolor(white) ilcolor(white) lcolor(white));
```

This produces the figure in the top panel of the marginal effect plot shown on the webpage. The first part of the command.

```
graph twoway hist changenonslav, width(0.5) percent color(gs14) yaxis(2)
```

overlays a histogram on the marginal effect plot, sets the width of the bars, indicates that we want the bars to represent the *percent* of observations, sets the color of the bars, and indicates that the second vertical axis on the right will be associated with the histogram. The second part of the command,

```
scatter where changenonslav if tag_nonslav,
plotr(m(b 4)) ms(none) mlabcolor(gs5) mlabel(pipe) mlabpos(6) legend(off)
```

overlays the rug plot. The third part of the command,

```
line combx MVZ, clpattern(solid) clwidth(medium) clcolor(black) yaxis(1)
```

plots the marginal effect of X on Y across the observed values of Z, and associates it with the first vertical axis on the left. The fourth part of the command,

```
line upperx MVZ, clpattern(dash) clwidth(thin) clcolor(black)
```

plots the upper bound of the confidence interval. The fifth part of the command,

```
line lowerx MVZ, clpattern(dash) clwidth(thin) clcolor(black)
```

plots the lower bound of the confidence interval. The sixth part of the command,

```
line yline MVZ, clwidth(thin) clcolor(black) clpattern(solid)
```

plots the horizontal line at 0. The remaining lines serve various purposes, such as indicating how the axes should look.

```
line yline MVX, clwidth(thin) clcolor(black) clpattern(solid)
,
    xlabel(30 40 50 60 70 80 90 100, nogrid labsize(2))
    ylabel(-1 -.75 -.5 -.25 0 .25 .5, nogrid labsize(2))
    ylabel(0 5 10 15 20 25 30, axis(2) nogrid labsize(2))
    yscale(noline alt)
    yscale(noline alt axis(2))
    xscale(noline)
    legend(off)
    xtitle("", size(2.5))
    ytitle("", axis(2) size(2.5))
    xsca(titlegap(2))
    ysca(titlegap(2))
    scheme(s2mono) graphregion(fcolor(white) ilcolor(white) lcolor(white));
```

This produces the figure in the bottom panel of the marginal effect plot shown on the webpage.

I prefer to take the two figures that have been created and put them in some other software to edit them – add labels etc. However, you can change the command lines that produce the figures directly in **Stata** to make them look exactly how you want them to.
